Abstract

Objective: To verify parents'/caregivers' perceptions of changes in their children's development during the COVID-19 pandemic and factors associated with such perceptions. Methods: Cross-sectional study using an online survey made available to parents/caregivers of children between 0-7 years old, from September 2021 to March 2023 in two Brazilian states. Respondents answered questions about their perceptions regarding their children's neurodevelopment, and worsening of neurodevelopment during the COVID-19 pandemic. Validated questionnaires such as M-CHAT, "Swanson, Nolan and Pellham," and "Strengths and Difficulties "were applied according to age. Comparisons were made using the chi-square test or Fisher's exact test, and Poisson regression was used in the univariate analysis and in the multivariate analysis. Results: Data from 589 children were obtained, 49.7% aged 0-3 years and 50.3% 4-7 years. Of the 0-3 age group, 50 (17.1%) were perceived as having abnormal neurodevelopment, and 79 (27.0%) as having worsened neurodevelopment during the pandemic. Of the 4-7 year group, 76 (25.7%) were perceived as having abnormal neurodevelopment, and 104 (35.1%) as having worsened their neurodevelopment. Significant risk factors associated with the perception of abnormal neurodevelopment were maternal schooling, the child's sex and age; for the perception of worsening neurodevelopment were the child's sex and age, low socioeconomic status, degree of social isolation, and death in the family due to COVID-19.

Conclusion: Data from the present study showed that parents/ caregivers' perception of normal neurodevelopment was significantly higher than their recognition of abnormalities. In addition, a significant percentage perceived a worsening during the COVID-19 pandemic.

1 Introduction

The COVID-19 pandemic, which occurred between 2020 and 2 3 2021, has affected the pediatric population in many ways. The impact began with the interruption and limitation of 4 social interaction, including the closure of schools, leading 5 to a change in routine with intense home confinement, cul-6 minating in various behavioral, psychological and neurode-7 velopmental repercussions.¹⁻ 8 9 Several studies were published during and after the pan-

demic, showing an increase in sleep problems in children and adolescents, an impact on relationships due to the deprivation of social interaction with peers, as well as limited opportunities for physical and creative activities. In addition, they report behavioral changes and mood swings in children, especially those diagnosed with ASD (autism spectrum disorder).^{5–7}

17 Mental health in the pediatric population has become more visible as a result of the changes identified. Studies 18 suggest an increase in neurobehavioral disorders, such as 19 associations with agitation, restlessness, and difficulty with 20 attention/concentration, emotional problems, aggressive 21 behavior, and an impact on social skills. Another aspect that 22 has been widely observed and referenced is the increase in 23 the time children are exposed to and use electronic devices, 24 as well as sleep problems during home confinement.^{3,4,8–10} 25

Due to the findings previously described, the aim of this study was to verify parents'/caregivers' perceptions of changes in their children's development during the COVID-19 pandemic and factors associated with such perceptions. A secondary aim was to compare among states eventual differences in this perception.

The authors hypothesized that differences between perception of worsening and perception of abnormality in the neurodevelopment of children during the COVID-19 pandemic might occur.

36 Methods

37 Type of study and data collection

This is a cross-sectional observational study with a target 38 population of children aged 0-7 years, with the partici-39 pants/respondents of the research being the parents/care-40 givers of this target population. The research was conducted 41 in the city of Porto Alegre, located in the state of Rio Grande 42 do Sul (RS), in southern Brazil, and in the city of Fortaleza, 43 44 located in the state of Ceará (CE), in northeastern Brazil. 45 These states were chosen for convenience and because both 46 had adopted preventive and restrictive measures as a contingency plan to deal with the pandemic, which were widely 47 followed by the population.^{11,1} 48

The data were collected using an online questionnaire 49 made available by the digital data collection platform 50 (online survey software) Qualtrics[®] (www.qualtrics.com). 51 The online format was chosen in order to collect data simultaneously in the two different cities. This study was 53 approved by the Research Ethics Committee of the Pontifical 54 Catholic University of Rio Grande do Sul (PUCRS) and is registered on the Brazil Platform under the number 56 47217921.2.0000.5336. 57

Respondents were invited to participate by advertising 58 the survey on the digital social media of the Pontifical Catho-59 lic University of Rio Grande do Sul and the Brain Institute of 60 Rio Grande do Sul, radio spots and local/state television, as 61 well as posters and folders with QR codes and links to the 62 survey displayed in schools and pediatric clinics in the city of 63 Porto Alegre. An active search for respondents was also car-64 ried out, with the questionnaire being applied in person in 65 pediatric care settings linked to the PUCRS School of Medi-66 cine (Basic Health Units and the Hospital São Lucas PUCRS 67 Clinical Center). In Fortaleza, dissemination also took place 68 via social media, with the access link being sent out, as well 69 as posters and folders with QR codes displayed in public and 70 private pediatric clinics and institutions. The active search 71 was conducted in basic health units, where electronic devi-72 ces were made available on site directly by the researchers 73 themselves. The guestionnaire was open for responses 74 between September 2021 and March 2023, with no request 75 for respondents to access the survey again. 76

Protocols and scales

Consent was obtained by means of a form (Informed Consent 78 Form - ICF) applied at the beginning of the online question-79 naire, after a brief descriptive explanation of the function-80 ing and purpose of this study. Respondents could only 81 proceed with the survey, accessing the questions in the questionnaire, after agreeing to take part in the study and agreeing to the online ICF by clicking on "I agree to take part in 84 this study". If they did not agree to take part, they were directed to the thank-you page. 86

77

After accepting and agreeing, the respondent was ini-87 tially directed to collect sociodemographic data, followed 88 by questions related to the history and course of pregnancy, 89 prenatal care, childbirth, the neonatal period, and the 90 child's health. In the sequence come questions related to 91 neurodevelopment, according to the age group. First, the 92 respondents state their perception regarding their children's 93 neurodevelopment compared to children of the same age 94 group, and also whether they have perceived a worsening in 95 their children's neurodevelopment during the COVID-19 pan-96 demic. The variables related to the assessment of neurode-97 velopment were based on the Denver Scale II, which was 98 adapted into the form of a questionnaire, and on the Child 99

Jornal de Pediatria xxxx;xxx(xxx): xxx-xxx

Development Form of the Early Childhood for Healthy Adults
 program (PIPAS).¹³⁻¹⁶

The interviewees were then directed to specific question-102 naires on behavioral and neurodevelopmental disorders, all 103 previously validated for Brazilian Portuguese. Given that 104 early signs of autism spectrum disorder (ASD) can be identi-105 fied in young children, the "Modified Checklist for Autism in 106 107 Toddlers" (M-CHAT) scale was used, which is recommended for children between 18 and 24 months of age. According to 108 the total score of the M-CHAT, children were classified as 109 low risk for ASD (0-2 points); moderate risk (3-6 points), and 110 high risk (7-23 points) for ASD.^{17–21} 111

The MTA-SNAP IV scale (shortened version of the Swan-112 son, Nolan and Pellham Questionnaire) was used to assess 113 the symptoms of attention deficit hyperactivity disorder 114 (ADHD) in children aged 4 and older, the recommended age 115 for such screening. It consists of 26 items divided into three 116 subscales: inattention, hyperactivity/impulsivity and oppo-117 sitional/challenging behavior. The score for each subscale 118 was added together to generate a raw score according to 119 120 the following classifications: clinically non-significant symp-121 toms (< 13 points); mild symptoms (13-17 points); moderate symptoms (18-22 points); severe symptoms 122 (23-27 points).²²⁻²⁴ 123

To assess and screen for mental health problems in chil-124 dren aged 4 and over, the authors used the "Strengths and 125 Difficulties Questionnaire" (SDQ) - parent version. This ver-126 sion consists of 25 items distributed in 5 subscales (emo-127 tional symptoms, conduct problems, hyperactivity, 128 relationship problems with peers, and pro-social behavior). 129 The SDQ was classified according to the total difficulty score 130 as normal (0-13 points), borderline (14-16 points), and 131 abnormal (17-40 points).^{25,26} 132

The last battery of questions referred to the situation of 133 restrictions related to the COVID-19 pandemic in the respond-134 ent's city, and also how the family behaved during the pan-135 demic period, as well as addressing the use of electronic 136 devices and the time the child was exposed to screens 137 through two specific questions. At the end of the question-138 naire, an automatic message was generated confirming that 139 the questionnaire had been completed and thanking them for 140 taking part in the survey, along with an information table on 141 142 warning signs of neurodevelopmental problems. For data analysis, the authors only included data from respondents 143 who completed the questionnaire completely and to the end. 144

145 Sample calculation and statistical analysis

A total sample size of 550 children was calculated to test 146 whether there is a difference between the percentages of 147 perception of worsening and perception of abnormality in 148 the neurodevelopment of children during the COVID-19 pan-149 demic between the groups, generated from the classifica-150 tions of various characteristics under study (including 151 income, maternal education, maternal age, sex of the child, 152 among others). The calculation considered groups of similar 153 size, power of 80%, significance level of 5%, baseline per-154 155 centage of perception of worsening or abnormality of 22% 156 and prevalence ratio of at least 1.5 as the minimum relevant 157 effect.

158 The values observed for the two outcomes considered 159 (perception of worsening and perception of abnormality in neurodevelopment) were described by count and percentages between the groups formed by the classifying variables, including their distribution among the states in the sample. All initial comparisons were carried out using the Chi-square test or Fisher's exact test, when necessary.

Using Poisson regression, the prevalence ratio of perception of worsening or abnormality in neurodevelopment, its 166 95% confidence interval, and the p-value were obtained for 167 each classifying variable. All the variables that showed p < 1680.20 in the univariate analysis were included in a multivariable Poisson model to adjust the effects, obtaining the same 170 statistics as above. 171

The respondents' perceptions of worsening and abnormal- 172 ity in neurodevelopment were compared with the reference 173 values of the selected screening scales, M-CHAT, SDQ and 174 SNAP. This resulted in sensitivity rates and false positive 175 rates. Sensitivity rates indicated the extent to which 176 respondents reported perceiving worsening and/or abnor-177 mality in the neurodevelopment of children classified as 178 moderate/high risk (or similar denomination) by the 179 selected scale. False positive rates indicate the extent to 180 which respondents reported perceiving worsening and/or 181 abnormality in the neurodevelopment of children classified 182 as low risk (or similar denomination) by the selected scale. 183

All statistical procedures were carried out using the IBM-SPSS version 25.0 program. Findings with a value of P<0.05 were considered statistically significant.

Results

In total, the survey had 496 respondents, 220 from RS and 188 276 from CE. The survey thus resulted in 589 children, 271 189 from RS and 318 from CE, as each respondent could include 190 more than one child during the course of answering the 191 questionnaire. 192

187

Table 1 shows the sociodemographic data of both the 193 respondents and the children. In both states, the survey 194 respondent was predominantly the child's mother and there 195 was a significant difference between the states (p < 0.001). 196 showing that mothers in RS were younger, and their school-197 ing was lower (p < 0.001). With regard to self-reported 198 monthly income, in CE there was a predominance of higher 199 incomes among the respondents (p < 0.001), and in RS there 200 was a predominance of Social Program participants 201 (p = 0.012). Emphasizing the pandemic context, in the CE, 202 there was greater compliance with local guidelines for social 203 isolation, with a significant difference between the groups 204 (p = 0.001). The reported cases of COVID-19 diagnoses in the 205 family were higher in CE than in RS, (p = 0.001), as were the 206 cases of COVID-19 deaths in family members (p = 0.019). 207 With regard to children, there were statistically significant 208 differences in the following variables: gender (p = 0.001), 209 with a predominance of males in CE (61.0%) and females in 210 RS (52.8%); age group (p = 0.005), with older children pre-211 dominating in CE; and schooling (p < 0.001), with a higher 212 number of children who were not attending school in RS. 213

Of the 589 children, 293 (49.7%) were in the 0-3 years age 214 group and 296 (50.3%) were in the 4-7 years age group. 215 Among the children aged 0 to 3, respondents perceived 50 216 (17.1%), as having abnormal neurodevelopment, and 79 217 (27.0%) worsened their neurodevelopment during the 218

pandemic. Among children aged 4 - 7, 76 (25.7%) were initially perceived as having abnormal neurodevelopment, and in 104 (35.1%) responders perceived a worsening on neurodevelopment worsened during the COVID-19 pandemic.

Comparing both states (RS and CE) and both age groups, there was an increased perception of abnormal neurodevelopment and worsening neurodevelopment during the pandemic in the age group 4-7. Regarding states, this perception of CE was significantly higher than in RS (p < 0.001).

Table 2 shows the univariate and multivariable regression analyses regarding the perception of worsening in children's neurodevelopment during the COVID-19 pandemic. In the uni-230variate analysis, significance was observed in relation to the231variables family income, maternal schooling, sex of the child,232age group of the child, having been in social isolation, and233cases of death from COVID-19 in the family. After adjustment,234the variables maternal schooling, sex of the child and age235group of the child remained significant, proving to be risk fac-236tors associated with the outcome of perception of worsening237neurodevelopment during the COVID-19 pandemic.238

Table 3 shows the univariate and multivariable regression 239 analyses regarding the perception of abnormal 240

Table 2 Respondents' perception of worsening neurodevelopment during the COVID-19 pandemic.

COVID- 19, disease caused by the coronavirus; N, total; no., perception of worsening; PR, prevalence ratio; CI, confidence interval; P, statistical significance; Ref, reference group; MW, minimum wage; HS, high school; PG, postgraduate; (*) all variables with a p-value < 0.20 in any of their categories were included in the multivariable model.

neurodevelopment compared. In the univariate analysis, the 241 variables family income, gender of the child, age group of 242 the child, participation in a Social Program, having been in 243 social isolation and cases of death from COVID-19 in the fam-244 ily reached a statistical significance. In the multivariable 245 analysis, after adjustment, the variables sex of the child, 246 age group of the child, participation in a Social Program, 247 having been socially isolated and cases of death by COVID-19 248 in the family remained significant. 249

According to Table 4, the respondents generally agreed 250 more with the normal/low risk classifications of the scales 251 used. The greatest predominance of agreement between 252 perception of abnormality and risk classification was 253 254 observed in the Inattention subscale of the SNAP scale, mod-255 erate/severe signs (68.6%). As for the respondents' percep-256 tion of worsening in children's neurodevelopment during the pandemic, agreement was higher with the risk classification, 257 also of the Inattention subscale of the SNAP scale, moder-258 ate/severe signs (77.1%). 259

In addition, the sensitivity rate and the false positive rate of the comparisons between the respondents' perceptions and the scale ratings were calculate the highest sensitivity rate was obtained between the SNAP (Inattention) scale and 263 respondents' perceptions of abnormal neurodevelopment 264 (68.6%) and worsening neurodevelopment during the pan-265 demic (77.1%). In other words, the respondents showed a 266 perception of abnormality and worsening in development in 267 children who were classified as at risk by this scale. The low- 268 est false positive rate was obtained between the M-CHAT 269 scale and respondents' perceptions of abnormal neurodevel- 270 opment (8.3%) and worsening neurodevelopment during the 271 pandemic (16.7%). This means that respondents reported 272 perceiving abnormal neurodevelopment and worsening neu-273 rodevelopment in children who were classified by the scale 274 as low risk. 275

Discussion

This study provides information about the perceptions of 277 parents and/or caregivers regarding the neurodevelopment 278 of their children during the COVID-19 pandemic and the risk 279 factors associated with such perceptions. It also presents 280 the sensitivity rates and false positive rates of these 281

Table 3 Perception of neurodevelopmental abnormality by respondents during the COVID-19 pandem	demic.
--	--------

COVID-19, disease caused by the coronavirus; N, total; no., perception of neurodevelopmental abnormality; PR, prevalence ratio; CI, confidence interval; P, statistical significance; Ref, reference group; MW, minimum wage; HS, high school; PG, postgraduate; (*) all variables with a p-value < 0.20 in any of their categories were included in the multivariable model.

perceptions in relation to the results of screening scales forneurodevelopmental disorders.

In general, the respondents' perception of normal neuro-284 development is higher than their recognition of abnormal 285 neurodevelopment. Regarding the perception of worsening 286 neurodevelopment during the COVID-19 pandemic, this was 287 reported in both states, although there was a greater pre-288 dominance of this perception in the 4-7 years age group. 289 Due to the impact of the COVID pandemic in many aspects of 290 life, this topic has also been investigated in other countries, 291 with some studies applying similar methodology. 292

A cross-sectional study carried out in Turkey assessed psy-293 294 chological and behavioral changes in children at different 295 ages (early childhood, n = 249; second childhood, n = 193; and 296 adolescence, n = 399) before and during the COVID-19 pandemic, from the perspective of their parents' perceptions, 297 using an online questionnaire. The study found that parents 298 predominantly perceived sleep-related problems in early 299 childhood, behavioral changes and psychological symptoms in 300 later childhood, and behavioral and psycho-emotional 301 changes, as well as cognitive changes in adolescents.²⁷ 302

In a cohort study carried out in Japan, with a sample of 303 887 children, 447 in the 1-3 years group and 440 in the 3-304 5 years group, the perception of negative impact varied. In 305 the 1-3 age group, the exposed cohort did not show a nega- 306 tive association between the pandemic and general develop-307 ment. In contrast, in the 3-5 age group, children were 4.39 308 months behind in overall development at age 5 compared to 309 controls, in all subdomains (broad motor, fine motor, recep-310 tive language, expressive language, language concepts, 311 social relationships with children, social relationships with 312 adults, and discipline).²⁸ Similarly, in the present study, the 313 greatest impacts were reported in older children, aged 4-7. 314

A Brazilian cross-sectional study analyzed, through the 315 perception of family members who answered an online questionnaire, the effects of a lack of school environment during 317 the pandemic on the development of their children aged 318 between 1-5 years. Results showed that the socio-emotional 319 aspect was the most negatively affected (this perception 320 was more intense in the group of children over three years 321 old), followed by the cognitive-linguistic aspect. Some 322 aspects were mentioned as having had a positive impact, 323

Jornal de Pediatria xxxx;**xxx(xxx):** xxx-xxx

Table 4 Comparison between respondents' perceptions and ratings by the selected scales.

Perceptions – Scales	Total
Perceptions – M-CHAT, no./total no. (%)	(N = 79)
Abnormality – Moderate, hight risk	8/31 (25.8)
Normality – Low risk	44/48 (91.7)
Worsening in the pandemic – Moderate, hight risk	10/31 (32.3)
Perceptions – SDQ, no./total no. (%)	(N=296)
Abnormality – Abnormal	52/153 (34.0)
Normality – Normal, boderline	119/143 (83.2)
Worsening in the pandemic – Abnormal	64/153 (41.8)
Perceptions – SNAP (Inattention), no./total no. (%)	(N=296)
Abnormality – Moderate, severe	24/35 (68.6)
Normality — No signs, mild signs	209/261 (80.1)
Worsening in the pandemic – Moderate, severe	27/35 (77.1)
Perceptions – SNAP (Hyperactivity, impulsivity), no./total no. (%)	(N=296)
Abnormality – Moderate, severe	14/39 (35.9)
Normality — No signs, mild signs	195/257 (75.9)
Worsening in the pandemic – Moderate, severe	19/39 (48.7)
Perceptions – SNAP (Oppositional, challenging behavior), no./total no. (%)	(N=296)
Abnormality – Moderate, severe	5/23 (21.7)
Normality — No signs, mild signs	202/273 (74.0)
Worsening in the pandemic – Moderate, severe	6/23 (26.1)

M-CHAT, Modified Checklist for Autism in Toddlers scale; SDQ, Multimodal Treatment Study of Children with Attention-Deficit Hyperactivity Disorder scale; SNAP, Strenghs and Difficulties Questionnaire scale; no., respondents' perceptions; total no., classification by the scale; N, total number of children covered by the scale.

324 with the cognitive-linguistic aspect being perceived as more positive than the motor and socio-emotional aspects; how-325 ever, it should be noted that the number of respondents who 326 did not identify positive effects was higher than those who 327 did not perceive negative effects. However, in the percep-328 tion of the respondents, with regard to child development, 329 the negative impacts of the pandemic were greater than the 330 positive ones, regardless of the age group assessed.²⁹ 331

A cross-sectional study carried out in the United States involving 37 subjects (health professionals, childcare providers and parents), showed their concern about the limitations of the pandemic impacting social interactions, the lack of access to peer models, and fewer opportunities for physical exploration and creative activities to promote child development.⁷

In order to demonstrate these impacts on development 339 and with an emphasis on the first year of life, a cohort study 340 carried out in the United States examined the neurodevelop-341 ment of babies born during the pandemic, at birth, and at 6 342 months of age, children of mothers infected with and moth-343 ers not infected with SARS-CoV-2. Using the Ages & Stages 344 Questionnaire 3rd Edition (ASQ-3) protocol, it was found 345 that in utero exposure to maternal SARS-CoV-2 infection was 346 not associated with significant differences in any ASQ-3 sub-347 domain. However, compared to the historical cohort, infants 348 born during the pandemic had significantly lower scores in 349 the domains of broad and fine motor skills and personal-350 social skills at 06 months of age.³⁰ 351

Further, a systematic review and meta-analysis evaluated the association of birth and development during the COVIDpandemic found an increased risk of impaired neurodevelopment among infants up to 12 months, predomi-355 nantly in aspects of communication and interpersonal relationships.³¹ 357

In relation to the studies that used similar methodology 358 but focused on populations with neurodevelopmental disorders, it is worth highlighting those described below. 360

A study of 506 Slovak families, 236 of whom had children 361 diagnosed with ASD, monitored changes in children's behav-362 ior during the three waves of the COVID-19 pandemic. The 363 findings showed an increase in inappropriate and maladap-364 tive behaviors in both neurotypical children and children 365 diagnosed with ASD, with minimal changes during the third 366 wave in children with ASD, which could be explained by the 367 greater availability of therapy during this period for such 368 children.6 369

A longitudinal study, carried out in Australia, examined 370 the impact of COVID-19 restrictions among 213 children aged 371 5 to 17 with attention deficit/hyperactivity disorder. Based 372 on an online questionnaire completed by parents, it was 373 found that compared to pre-pandemic, children had less 374 exercise and less time outdoors, as well as less enjoyment of 375 activities, while television, social media, and gaming time 376 increased, with an increase in sad/depressed mood and lone-377 liness. This study also highlighted parents' reports of positive 378 changes for their children, including more family time.³² 379

In the present study, the findings showed that the most 380 significant risk factors associated with the perception of 381 worsening neurodevelopment were the mother's level of 382 education, the child's gender, and the child's age group. 383 Regarding the perception of abnormal neurodevelopment, 384 the most significant associated factors were the child's gen-385 der, age group, family participation in a social program, the 386

S.R. Ibiapina, T.M. Werle, M.M. Giongo et al.

family having been socially isolated during the COVID-19pandemic, and losing a family member for COVID-19.

A previous study on risk factors for infant motor develop-389 ment showed that mothers with higher levels of education 390 have more knowledge and concern about the adequate stimu-391 lation of their children, devoting more attention to their devel-392 opment.³³ In this study, it was observed that the higher the 393 394 level of maternal education correlated with greaterthe perception of worsening in the child's neurodevelopment during 395 the COVID-19 pandemic, corroborating the previous report. 396

Another study, with data collected at the beginning of the 397 pandemic, found that parents and caregivers reported sig-398 nificant concerns about their children's development during 399 the pandemic. The study points to possible delays in cogni-400 tive development, difficulties in social interaction, and 401 behavioral regressions. The environment of isolation and 402 reduced external stimuli was identified as a determining fac-403 tor. Besides, adverse life experiences related to family, envi-404 ronment, and society were considered environmental risks 405 406 for problems in child development. Some of these adverse 407 experiences include poor health conditions, lack of social 408 and educational resources, maternal education, and family stress.³⁴ In the present study, it was found that family partic-409 ipation in a social program, a factor that refers to restricted 410 access to social resources, was a risk factor associated with 411 the perception of neurodevelopmental abnormality. In other 412 words, in this study, families participating in a social pro-413 gram reported a greater perception of abnormality than 414 families not participating in a social program. Further, the 415 present study showed a higher prevalence of perceived neu-416 rodevelopmental abnormality among respondents who said 417 that they remained in social isolation, that is, they stayed at 418 home with their children, which allowed them more time to 419 420 observe and perceive them.

It is worth highlighting some limitations of this study, such 421 as the heterogeneous socio-demographic distribution of the 422 sample population, with a predominance of respondents 423 from a more privileged social level among residents of Ceará. 424 The sample refers to only two Brazilian states and, espe-425 cially in the state of Ceará, includes respondents with a very 426 high level of education in relation to the Brazilian popula-427 tion. This aspect may influence the perception of people 428 429 with higher levels of education in a different way. Another limitation is that there was no precise information on previ-430 ous diagnoses of neurodevelopmental disorders in the chil-431 dren under study. On the other hand, one of the strengths of 432 this study is that the authors compared the respondents' per-433 ception with standardized scales and showed agreement at 434 435 different levels.

In conclusion, this study found that parents' and/or care-436 givers' perception of normal neurodevelopment was signifi-437 cantly higher than their recognition of abnormalities. It also 438 showed that these caregivers perceived a worsening in their 439 children's neurodevelopment during the COVID-19 pan-440 demic. Further, the risk factors for the perception of abnor-441 mal neurodevelopment were related to sex (male) age 442 group (4-7 years), family socioeconomic level, degree of 443 444 family isolation and the decrease of family members during 445 the COVID-19 pandemic. For the perception of worsening in 446 children's neurodevelopment, the risk factors found were 447 the child being male, being in the 4-7 age group, and mater-448 nal schooling.
